Space allocation works differently than in traditional filesystems and volume managers.

Filesystems are free to allocate blocks from the whole pool - no preallocated filesystem space.

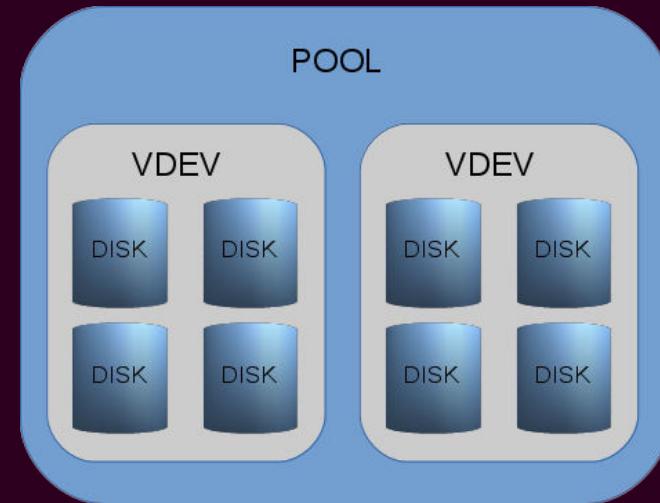

# Common pool layouts - RAIDZ, RAIDZ-2

One vdev

Multiple vdevs

# Here be dragons

- Space utilization reporting: `zfs -o space,`
- Pool health
- Deduplication

# ZFS as root filesystem

1. Cheap and quick clones of running system for experimentation
2. As above, but for preparing a backup
3. “Golden image” copy of system

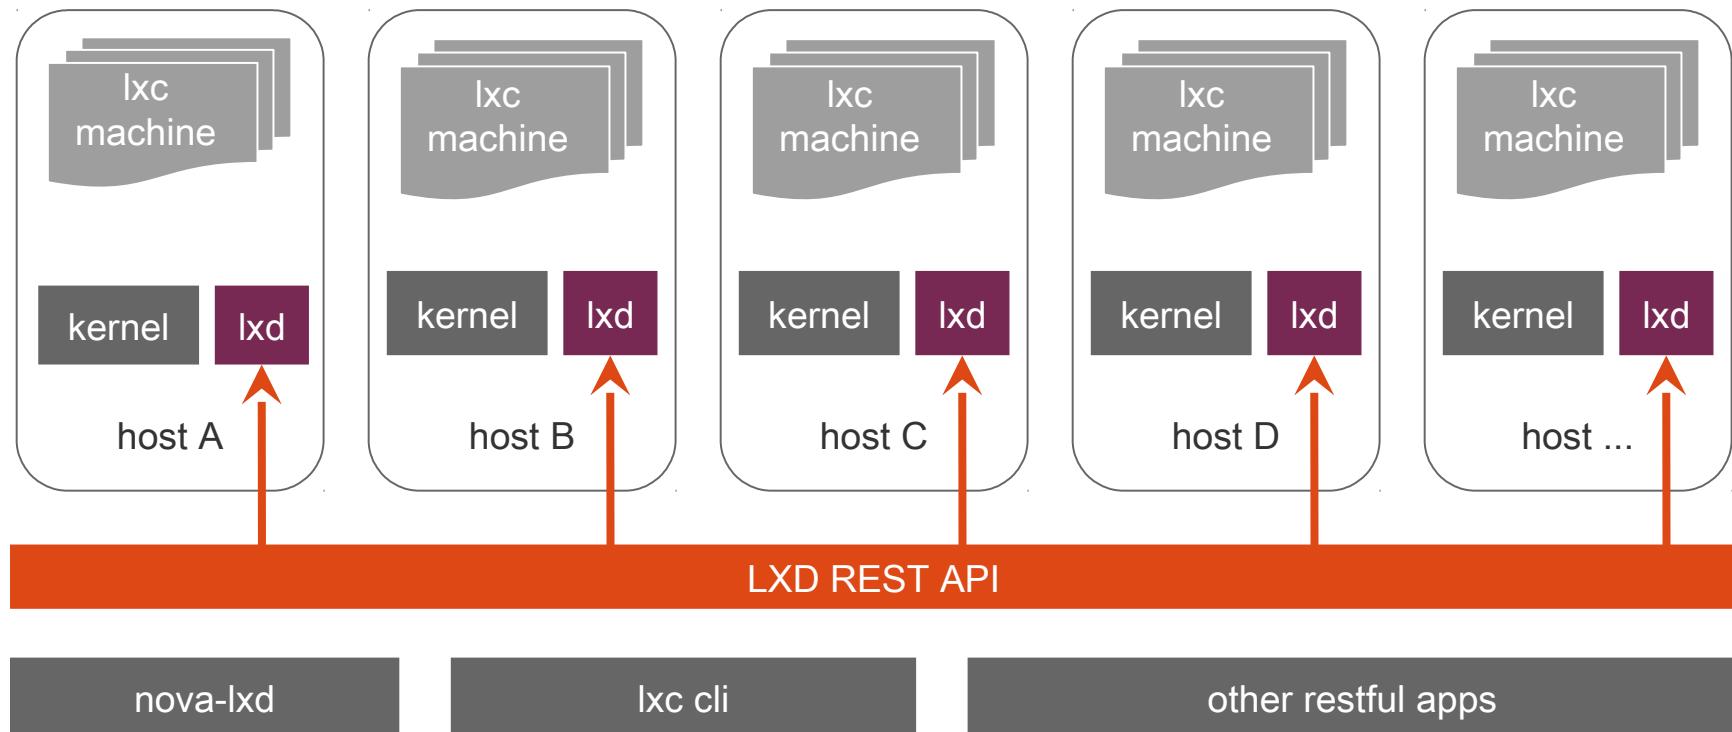

Virtual Machines

Process containers

Machine containers

Bare metal

# LXD is Canonical's container hypervisor

# LXD and ZFS

1. ZFS as a storage backend to LXD
2. Snapshot, restore
3. Compression on the fly
4. Deduplication (don't forget to monitor closely)
5. Simplified backup
